Vision

Our project is a convenient, flexible, and customizable system for tracking tasks (Issue Tracking System). It's being created as a universal tool suitable not only for technical specialists but also for ordinary people, families, or small teams from any field.

The main idea of the system is to adapt to the user's needs. It can be used to simply keep a list of household chores for the weekend, or to build a complex workflow with checks and access rules. The system doesn't impose rigid constraints, allowing users to decide for themselves how they want to organize their tasks, control deadlines, and manage their progress.

Functional requirements

1. **Working with tasks:** Users must be able to create, view, edit, and delete tasks.
2. **Task content:** Each task must include the following data:
 - Title and type (e.g., bug, idea, household task).
 - Detailed description with the ability to nicely format text, insert images and tables.
 - Author and assignee.
 - Current status and priority (importance).
 - Start date and completion date (deadline).
3. **Collaboration:** Multiple people can work in the system at once, with each person able to be assigned their own role and access rights
4. **Process configuration:** Users can define their own task statuses and the rules by which they can change. (For example, it can be set up so that only a reviewer has the right to move a task to the "Done" status.)
5. **Grouping:** Tasks can be combined into logical groups — sprints.
6. **Display and search:** All tasks can be shown on a shared board, filtered as needed, and sorted by importance, deadlines, and other parameters.

Non-functional requirements

1. **Usability:** The text editor within a task must be visual and simple, so that anyone can insert an image or table without needing to know special technical commands.
2. **Reliability:** The system must strictly enforce the rules configured by users (for example, blocking an attempt to change a task's status if the person doesn't have the rights to do so).
3. **Extensibility:** The system's architecture must be built so that new features can easily be added in the future (in the second stage of development), such as reports or custom fields.
4. **Concurrent work:** If two users simultaneously open and try to edit the same task, the system must handle this correctly without data loss.

Domain vocabulary

- **Task:** The main element of the system. It can be anything: a work assignment, a bug fix in code, or a plan to buy groceries for home.
- **Lifecycle:** The path a task takes from the moment of creation to full completion (for example, the chain "New" → "In Progress" → "Done").
- **Transition rule:** A configured condition specifying who can change a task's lifecycle stage, and when. For example, only the person who created a family task can close it.
- **Assignee:** The person assigned to complete a specific task.
- **Sprint:** A group of tasks that need to be completed within a certain period (e.g., "This Week's Plans" or "Renovation").
- **Board:** A visual representation of tasks as columns, so you can see at a glance what's already done and what's still ahead.
